Abstract

We derive formulas for counting certain classes of vacua in the string/M theory landscape. We do so in the context of the moduli space of M-theory compactifications on singular manifolds with G_2 holonomy. Particularly, we count the numbers of gauge theories with different gauge groups but equal numbers of $U(1)$ factors which are dual to each other. The vacua correspond to various symmetry breaking patterns of grand unified theories. Counting these dual vacua is equivalent to counting the number of conjugacy classes of elements of finite order inside Lie groups. We also point out certain cases where the conventional expectation is that symmetry breaking patterns by Wilson lines and Higgs fields are the same, but we show they are in fact different.

1. Introduction

In the study of compactification of string or M theory on Calabi–Yau (CY) or G_2 manifolds, it was believed for many years that one could find a particular CY or G_2 manifold from which the theory resulting from compactification would be the true vacuum: the Standard Model of particle physics. After a while, it became apparent that finding such a CY or G_2 manifold would be inordinately difficult due to the staggering number of possible manifolds, which form what is now known as the “string landscape”. The string landscape tied in with prior ideas related to the cosmological constant problem [1–5]. There was then a paradigm shift in the approach, from searching for a particular vacuum towards counting the many vacua of the landscape [6]. An extensive discussion of the issue of counting vacua, following which there was a surge of

literature about statistics of vacua, appeared in [6] (see also [7] and references therein). There, in lieu of a precise counting, statistical methods were used.

Some time before the paradigm shift of [6], the first author took the counting approach and found the first precise formula for counting string or M-theory vacua in the context of a study of the dynamics of M-theory compactified on singular spaces of G_2 holonomy that provide for gauge symmetry breaking [8].¹ The study of compactifications on singular manifolds was motivated by the realization that for smooth G_2 manifolds, compactification does not lead to any non-Abelian gauge theories [14–16] and thus is not useful in obtaining the ultimate vacuum, i.e. the Standard Model of particle physics. However, when a manifold of G_2 holonomy has an A, D, or E singularity – that is, a singularity of the form \mathbf{C}^2/Γ where Γ is a finite, discrete subgroup of $SU(2)$ – it is known via string dualities [17–19,15,16,20] that the four-dimensional physics contains a supersymmetric non-Abelian gauge theory with gauge group given by the ADE Lie group corresponding to the ADE singularity. Therefore, the study of compactification of M-theory on singular G_2 spaces could lead to potentially realistic physical theories; for recent examples, see [21–25].

The space of supersymmetric M-theory vacua can be thought of as the quantum moduli space of M-theories compactified on G_2 manifolds. When the G_2 manifolds are asymptotic to a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/\Gamma$, it has been shown [19,15,16,26] that the quantum moduli space is a Riemann surface that smoothly interpolates between three different classical limits: one of these classical limits corresponds to non-Abelian supersymmetric ADE gauge theories that arise from ADE singularities in the G_2 manifold, while the two others correspond to theories on a smooth G_2 manifold which does not admit any normalizable zero modes. Since theories with no normalizable zero modes have a mass gap, the smooth interpolation between such theories and non-Abelian supersymmetric gauge theories has been viewed as evidence supporting the statement that non-Abelian supersymmetric gauge theories have a mass gap [16,19,26,14].

This picture may be generalized to G_2 manifolds that are asymptotic to a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/\Gamma$ where Γ is a larger group such as $\Gamma = \Gamma_1 \times \Gamma_2 \times \Gamma_3 \in [SU(2)]^3$, where each Γ_i is a finite discrete subgroup of $SU(2)$. In this case, it was shown in [8] that the three classical limits appearing in the moduli space correspond to supersymmetric ADE gauge theories that admit a natural gauge symmetry breaking by Wilson lines² of a gauge group G of ADE type to a subgroup H . The moduli space then consists of disconnected branches classified by the number of $U(1)$ factors that appear in the subgroup H of G that remains after the gauge symmetry breaking. As in [8], we denote the branch with $s - 1$ $U(1)$ factors by $\mathcal{N}_{s,\Gamma}$. The number of $U(1)$ factors also corresponds to the number of zero modes that appear in the theory. One example stands out: when $\Gamma = \mathbf{Z}_5 \times \mathbf{Z}_q$ and q is prime to 5, we obtain the first manifestation via M-theory of Georgi–Glashow grand unification: an $SU(5)$ grand unified gauge group is broken by Wilson lines precisely to the gauge group of the Standard Model $SU(3) \times SU(2) \times U(1)$ [35,8,21]. Having a single $U(1)$ factor, this theory appears on the branch $\mathcal{N}_{2,\mathbf{Z}_5 \times \mathbf{Z}_q}$.

The smooth interpolation between any two points on a given branch can be interpreted as a duality between theories with different gauge groups H and H' but equal number of $U(1)$

¹ For counting of supersymmetric vacua in gauge theories via the Witten index, see [9–13] and references therein.

² The idea of symmetry breaking by Wilson lines dates back to the 1980s [27–30] and has appeared and re-appeared in the string/M/F theory literature. For some recent examples see [8,21,31–34].

factors. For example, if the G_2 space has an A_{n-1} singularity, we have an $SU(n)$ gauge theory which can be broken to s non-Abelian subgroups and $s - 1$ Abelian $U(1)$ factors via

$$SU(n) \longrightarrow \prod_{i=1}^s SU(n_i) \times U(1)^{s-1},$$

where $\sum n_i = n$. For fixed s , all these theories appear on a single branch and are interpreted as dual to each other. This same duality, originally obtained in [8] via M-theory compactifications, was later rediscovered in [36] via field theoretic methods.

The question now becomes, how many such theories, or – equivalently – semiclassical vacua, actually appear on each branch $\mathcal{N}_{s,r}$ of the quantum moduli space? Unlike the more general case of [6], where counting is not possible, a precise formula in the particular case of A_n singularities actually was presented already in [8] (without the derivation). As it happens, this formula constituted the first actual counting of vacua with gauge symmetry breaking in the string/M theory landscape context, and the first author has received requests for the derivation.

It is the purpose of this paper to provide the counting formulas not only for A_{n-1} singularities corresponding to the grand unified group $G = SU(n)$, but also to provide analogous formulas for $G = SO(n)$, $Sp(n)$, $U(n)$, and $O(n)$. The prudent reader would notice that these are the A, B, C, and D Lie groups, while the M-theory compactification we started with corresponds to gauge theories with A, D, or E gauge groups only. While the formulas we derive for A and D groups apply directly to the given M-theory compactifications on A and D singularities, the formulas for B and C groups do not seem at first sight to be directly related to any such compactification. However, we note that one may obtain the Dynkin diagrams corresponding to the B and C groups by folding the A or D Dynkin diagrams. Specifically, B_n may be obtained by folding D_{n+1} , and C_n may be obtained by folding A_{2n-1} [37]. Therefore, our formulas for B and C groups do apply to compactifications that allow for such folding action. Also, the formulas we obtain tell us new information about symmetry breaking patterns for grand unified theories (GUTs) that may be useful beyond the M-theory compactifications from which we obtained them.

In all the cases under consideration, the locus of the singularity in the manifold of G_2 holonomy is a cycle which has a non-trivial fundamental group, and it is the fundamental group which allows for the GUT symmetry breaking by Wilson lines. The same Wilson lines naturally induce a fractional three-form flux that can stabilize moduli [31], an important consideration when attempting to obtain Standard Model physics from string or M theory.

Note that the vacua we consider are supersymmetric; to reach the landscape of non-supersymmetric vacua, one needs to put in a supersymmetry breaking mechanism. Also, note that the specific manifolds of G_2 holonomy we consider are not compact; our discussion is relevant to M-theory on compact manifolds of G_2 holonomy with ADE singularities whose locus is a 3-cycle with non-trivial fundamental group [19,8].

This paper is organized as follows. In Section 2 we explain the connection between vacua and conjugacy classes. In Sections 3, 4, and 5 we derive the counting formulas for the unitary and special unitary groups, symplectic groups, and orthogonal groups, respectively. In Section 6 we point out a subtle difference in symmetry breaking patterns by Wilson lines and by adjoint Higgs fields. In a separate manuscript [39], the counting is addressed from a purely mathematical approach. We leave for future work the analogous counting in the exceptional compact Lie groups as well as in non-compact Lie groups.

Two of the quantities we derive, Eqs. (2) and (6), were obtained in [38] using the full machinery of Lie structure theory. Our methods are combinatorial and apply not only to simply

connected or adjoint groups as do the methods of [38], so we can obtain results about $O(n)$, $SO(n)$, and $U(n)$ in addition to $SU(n)$ and $Sp(n)$.

2. Vacua as conjugacy classes

In this section we show that counting vacua in the string/M theory landscape can be reformulated in terms of counting certain conjugacy classes in Lie groups.

Consider manifolds of G_2 holonomy that are asymptotic to a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/(\mathbf{Z}_p \times \mathbf{Z}_q)$, with $(p, q) = 1$. The manifold $\mathbf{S}^3 \times \mathbf{S}^3$ can be described [19,8] as a homogeneous space $SU(2)^3/SU(2)$ where the equivalence relation is

$$(g_1, g_2, g_3) \sim (g_1 h, g_2 h, g_3 h), \quad g_i, h \in SU(2).$$

A cone over this manifold may be obtained by “filling in” one of the three $SU(2)$ factors, that is, by allowing say $g_1 \in \mathbf{B}^4$ (a ball of radius 1 in four dimensions) rather than just $g_1 \in \mathbf{S}^3 \sim SU(2)$. The action of $\gamma \times \delta \in \mathbf{Z}_p \times \mathbf{Z}_q$ is then given by

$$(g_1, g_2, g_3) \mapsto (\gamma g_1, \delta g_2, g_3).$$

As shown in [8], when $(p, q) = 1$ the compactification of M-theory on such manifolds leads to semiclassical vacua that are either an $SU(p)$ gauge theory on a seven-dimensional locus of the form $\mathbf{R}^4 \times (\mathbf{S}^3/\mathbf{Z}_q)$, or an $SU(q)$ gauge theory on $\mathbf{R}^4 \times (\mathbf{S}^3/\mathbf{Z}_p)$.³ These gauge theories are the vacua that we will be counting in this paper.

We may also consider manifolds of G_2 holonomy that are asymptotic to a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/(\Gamma_1 \times \Gamma_2)$, where now the Γ_i are finite subgroups of $SU(2)$ that are not necessarily cyclic, i.e. they may be of D or E type as well. We still require $(|\Gamma_1|, |\Gamma_2|) = 1$ where $|\Gamma_i|$ denotes the number of elements in Γ_i .⁴ Since the DE groups all have even order, at least one of the Γ_i must be of A type, so we consider $(\mathbf{S}^3 \times \mathbf{S}^3)/(\Gamma \times \mathbf{Z}_q)$ with Γ an ADE group such that $(|\Gamma|, q) = 1$. We obtain vacua that are certain combinations of $SU(p)$, $SO(2n)$, and $E_{6,7,8}$ gauge groups living on cycles with (binary) cyclic, dihedral, tetrahedral, octahedral, and icosahedral fundamental groups.

All the vacua we will be counting are gauge theories living on a manifold M with non-trivial fundamental group $\pi_1(M)$ (in the above example, M was $\mathbf{R}^4 \times (\mathbf{S}^3/\mathbf{Z}_p)$ or $\mathbf{R}^4 \times (\mathbf{S}^3/\mathbf{Z}_q)$ and $\pi_1(M)$ was \mathbf{Z}_q or \mathbf{Z}_p). Therefore, these vacua admit Wilson lines (flat connections), that is, homomorphisms of the fundamental group into the gauge group, $U : \pi_1(M) \rightarrow G$, given by [40]:

$$U_\gamma = P \exp \int_\gamma A dx$$

where γ is a non-trivial loop in M and A is a flat connection. In the presence of a Wilson line, the gauge group G is broken to the subgroup $H_\gamma \subset G$ that commutes with U_γ :

$$H_\gamma = \{h \in G \mid h U_\gamma h^{-1} = U_\gamma\}.$$

For any other element γ' of the fundamental group for which $U_{\gamma'}$ is conjugate in the gauge group to U_γ , the remaining subgroup $H_{\gamma'}$ will be conjugate to H_γ and isomorphic to it. We will

³ The requirement that q and p are relatively prime ensures that the seven-dimensional loci are not singular.

⁴ Again, this condition ensures the smoothness of the seven-dimensional locus of the singularity.

be counting the theories that have distinct symmetry breakings, so we count each conjugacy class of Wilson lines only once. For example, when the fundamental group is \mathbf{Z}_q and the gauge group is $SU(p)$, a conjugacy class of Wilson lines is simply a conjugacy class consisting of elements of $SU(p)$ order dividing q , i.e. elements $x \in SU(p)$ such that $x^q = I$.

3. Counting vacua associated with unitary groups

In this section, we derive the formulas for the number of semiclassical vacua that appear in the moduli space of M-theory compactifications on singular spaces of G_2 holonomy that are asymptotic to a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/\mathbf{Z}_p \times \mathbf{Z}_q$.

Based on the previous section, this number is equal to the number of conjugacy classes of elements of order dividing q in $SU(p)$ (i.e. $x^q = 1, x \in SU(p)$) where p and q are relatively prime (or the same with p and q exchanged). In the process, we also count the number of such conjugacy classes in the full unitary group $U(p)$, where there are no constraints on p and q .

Since every conjugacy class of $U(p)$ or $SU(p)$ contains diagonal matrices, the problem reduces to counting inequivalent diagonal matrices. For both $U(p)$ and $SU(p)$, the diagonal entries are q th roots of unity, $e^{2\pi i k/q}$ with $k = 0, 1, \dots, q - 1$; for $SU(p)$, we have the additional condition that their product – the determinant of the matrix – must be unity.

We proceed through an example. Let $p = 7$ and $q = 4$. Partition p into q parts corresponding to the q possible values for the diagonal entries, keeping in mind that not all q roots of unity are required to appear. Consider the following diagram:

This diagram corresponds to the partition $\{n_k\} = (n_0, n_1, n_2, n_3) = (2, 3, 0, 2), \sum n_k = p$. This partition corresponds to the matrix $\text{diag}(\exp \frac{2\pi i}{4}(0, 0, 1, 1, 1, 3, 3)) = \text{diag}(1, 1, e^{\frac{2\pi i}{4}}, e^{\frac{2\pi i}{4}}, e^{\frac{2\pi i}{4}}, e^{\frac{6\pi i}{4}}, e^{\frac{6\pi i}{4}})$, which breaks $U(7)$ to $U(2) \times U(3) \times U(2) = SU(2) \times SU(3) \times SU(2) \times U(1)^3$. There is a bijection between such diagrams and inequivalent diagonal matrices in $U(7)$. Note that the exponents of the entries in the corresponding matrix are nondecreasing, so there is no danger of over-counting any equivalent diagonal matrices.

The above diagram has $p + q - 1$ dots, with $q - 1$ of them circled. The number of distinct such diagrams is given by

$$\binom{p + q - 1}{q - 1} = \binom{p + q - 1}{p}, \tag{1}$$

and this is the number of conjugacy classes of elements of order 4 or 2 in $U(7)$, or more generally the number of conjugacy classes of elements of order q or dividing q in $U(p)$. This number is also the number of “weak q -compositions of p ” [41].

Now impose $(p, q) = 1$ and turn to $SU(p) = SU(7)$. We must take into account the requirement that the determinant of the matrix must be unity. Consider the following set of $q = 4$ distinct partitions related to each other by cyclic permutations, their corresponding $U(7)$ matrices, and the sums of the diagonal exponents:

$$\begin{aligned} \{n_k^{(0)}\} &= (2, 3, 0, 2), & \text{diag}\left(\exp \frac{2\pi i}{4}(0, 0, 1, 1, 1, 3, 3)\right), & \sum kn_k^{(0)} \equiv 1 \pmod{4}, \\ \{n_k^{(1)}\} &= (3, 0, 2, 2), & \text{diag}\left(\exp \frac{2\pi i}{4}(0, 0, 0, 2, 2, 3, 3)\right), & \sum kn_k^{(1)} \equiv 2 \pmod{4}, \end{aligned}$$

$$\begin{aligned} \{n_k^{(2)}\} &= (0, 2, 2, 3), & \text{diag}\left(\exp\frac{2\pi i}{4}(1, 1, 2, 2, 3, 3, 3)\right), & \sum kn_k^{(2)} \equiv 3 \pmod 4, \\ \{n_k^{(3)}\} &= (2, 2, 3, 0), & \text{diag}\left(\exp\frac{2\pi i}{4}(0, 0, 1, 1, 2, 2, 2)\right), & \sum kn_k^{(3)} \equiv 0 \pmod 4, \end{aligned}$$

where $k = 0, \dots, q - 1$. It is no accident that exactly one of these four has determinant equal to unity (the fourth one), making it an element of $SU(7)$. More generally, for a given partition $\{n_k^{(0)}\}$, consider the following set of q distinct partitions:

$$\{n_k^{(j)}\} = \{n_{k+j}^{(0)}\}, \quad j, k = 0, 1, \dots, q - 1$$

(indices are understood mod q). The determinant of the corresponding matrix is given by

$$D_{\{n_k^{(j)}\}} = \exp\frac{2\pi i}{q}\left(\sum_{k=0}^{q-1} kn_k^{(j)}\right) = \exp\frac{2\pi i}{q}\left(\sum_{k=0}^{q-1} kn_{k+j}^{(0)}\right).$$

As we cycle through $j = 0, \dots, q - 1$, the sums differ from each other by multiples of $\sum_k n_k^{(j)} = p$:

$$\begin{aligned} D_{\{n_k^{(j)}\}} - D_{\{n_k^{(j+1)}\}} &= \sum_{k=0}^{q-1} (kn_k^{(j)} - kn_k^{(j+1)}) \\ &= \sum_{k=0}^{q-1} kn_{k+j}^{(0)} - \sum_{k=1}^q (k-1)n_{k+j}^{(0)} = -qn_{q+j} + \sum_{k=1}^q n_{k+j}^{(0)} \equiv p \pmod q. \end{aligned}$$

Since $(q, p) = 1$, by the Chinese remainder theorem, the sum $0 \pmod q$, which represents a matrix in $SU(p)$ and not just $U(p)$, appears exactly once. Therefore, to get the number of conjugacy classes in $SU(p)$ we must divide our previous formula by q :

$$\frac{1}{q} \binom{p+q-1}{p} = \frac{(p+q-1)!}{p!q!}. \tag{2}$$

Eq. (2) represents the number of semiclassical vacua appearing on the moduli space of M-theory compactifications on a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/(\mathbf{Z}_p \times \mathbf{Z}_q)$, as well as the number of inequivalent ways to break $SU(p)$ gauge symmetry by a \mathbf{Z}_q Wilson line.

As explained in the introduction, in addition to the total number of ways to break the gauge symmetry by Wilson lines, which is given by Eq. (1) for $U(p)$ and Eq. (2) for $SU(p)$, it is also of physical interest to count how many of these symmetry breakings result in a specified number of $U(1)$ factors in the remaining gauge group H . Let us denote this number of $U(1)$ factors by s , so that the symmetry breaking is of the form

$$U(n) \longrightarrow U(1)^s \times \prod_{i=1}^s SU(n_i)$$

or

$$SU(n) \longrightarrow U(1)^s \times \prod_{i=1}^{s+1} SU(n_i).$$

Again we show how to count through an example. We start with the full unitary group $U(p)$. Let $p = 7$ and $q = 4$ as before, and let $s = 2$. Consider the following diagram:

It corresponds to a partition of p into s non-zero parts, $\{n_a\} = (n_1, n_2) = (2, 5)$ ($\sum_{a=1}^s n_a = p$). Note that there is $1 = s - 1$ vertical dividing line. There are

$$\binom{p-1}{s-1}$$

different such partitions, also known as “ s -compositions of p ” [41]. To associate such a partition to a matrix, we must choose $s = 2$ eigenvalues out of the possible $q = 4$. There are

$$\binom{q}{s}$$

different such choices. Suppose we chose eigenvalues $e^{2\pi i/4}$ and $e^{6\pi i/4}$, which we denote by $\{\lambda_a\} = (\lambda_1, \lambda_2) = (1, 3)$. Then the diagonal matrix corresponding to this choice is $\text{diag}(\exp(2\pi i/4)(1, 1, 3, 3, 3, 3, 3))$, where as before we have ordered the exponents in non-decreasing order so as not to overcount. Note that we have not required here that p and q be relatively prime. So we have that the number of ways to break the gauge group $U(p)$ into subgroups that have exactly s $U(1)$ factors is

$$\binom{p-1}{s-1} \binom{q}{s} = \frac{s}{p} \binom{p}{s} \binom{q}{s}. \tag{3}$$

The calculation is modified for $SU(p)$, where we impose the condition that the determinant of the matrix is unity and $(p, q) = 1$. Continuing with the example $\{n_a\} = (2, 5)$, consider the following set of $q = 4$ choices of eigenvalues:

$$\begin{aligned} \{\lambda_a^{(0)}\} &= (1, 3), & \text{diag}\left(\exp\frac{2\pi i}{4}(1, 1, 3, 3, 3, 3, 3)\right), & \sum n_a \lambda_a^{(0)} \equiv 1 \pmod{4}, \\ \{\lambda_a^{(1)}\} &= (2, 0), & \text{diag}\left(\exp\frac{2\pi i}{4}(2, 2, 0, 0, 0, 0, 0)\right), & \sum n_a \lambda_a^{(1)} \equiv 0 \pmod{4}, \\ \{\lambda_a^{(2)}\} &= (3, 1), & \text{diag}\left(\exp\frac{2\pi i}{4}(3, 3, 1, 1, 1, 1, 1)\right), & \sum n_a \lambda_a^{(2)} \equiv 3 \pmod{4}, \\ \{\lambda_a^{(3)}\} &= (0, 2), & \text{diag}\left(\exp\frac{2\pi i}{4}(0, 0, 2, 2, 2, 2, 2)\right), & \sum n_a \lambda_a^{(3)} \equiv 2 \pmod{4}, \end{aligned}$$

where $a = 1, \dots, s$ and

$$\{\lambda_a^{(j)}\} = \{\lambda_a^{(0)} + j\}, \quad j = 0, 1, \dots, q - 1,$$

and all numbers are understood mod q . As before, it is no accident that exactly one of these (the second in this case) has determinant equal unity. The determinants of the corresponding matrices are given by

$$D_{\{\lambda_a^{(j)}\}} = \exp\frac{2\pi i}{q} \left(\sum_{a=1}^s n_a \lambda_a^{(j)}\right) = \exp\frac{2\pi i}{q} \left(\sum_{a=1}^s n_a (\lambda_a^{(0)} + j)\right). \tag{4}$$

As we cycle through $j = 0, \dots, q - 1$, the sums differ from each other by multiples of p :

$$D_{\{\lambda_a^{(j+1)}\}} - D_{\{\lambda_a^{(j)}\}} = \sum_{a=1}^s n_a \lambda_a^{(j+1)} - \sum_{a=1}^s n_a \lambda_a^{(j)} = \sum_{a=1}^s n_a = p.$$

When p and q are relatively prime, exactly one of the q sums in Eq. (4) will have determinant equal unity. So we divide Eq. (3) by q to obtain

$$\frac{1}{q} \binom{p-1}{s-1} \binom{q}{s} = \frac{s}{pq} \binom{p}{s} \binom{q}{s}, \tag{5}$$

which holds for $(p, q) = 1$ and represents the number of ways to break the gauge group $SU(p)$ into subgroups that have exactly $s - 1$ $U(1)$ factors. Each such breaking also represents a semi-classical point on the branch $\mathcal{N}_{s,\Gamma}$ of the moduli space associated with $\Gamma = \mathbf{Z}_p \times \mathbf{Z}_q$.

Note the symmetry under exchange of p and q in both Eq. (2) and Eq. (5). This symmetry implies a certain duality between the corresponding physical theories, see [8].

Putting together Eqs. (2) and (5) we now obtain

$$\binom{p+q-1}{p} = \sum_{s=1}^p \frac{s}{p} \binom{p}{s} \binom{q}{s} = \sum_s \binom{p-1}{s-1} \binom{q}{q-s}.$$

This is known as the Chu–Vandermonde identity [41]. This seems to be the first appearance of this identity in the context of counting string/M theory vacua, and its first appearance in the context of counting conjugacy classes of elements of finite order in a group G .

It is also possible to obtain formulas in the case $(p, q) \neq 1$ via a generating function approach [39]. For integers n and m that are not relatively prime, the number of conjugacy classes of elements of order m or dividing m in $SU(n)$ is

$$\frac{1}{m} \sum_{d|(n,m)} \phi(d) \binom{n/d + m/d - 1}{n/d},$$

where $\phi(d)$ is Euler’s function. This is also the number of ways to break $SU(n)$ gauge theory to a subgroup using a Wilson line of order m or dividing m . When we require that the remaining subgroup of $SU(n)$ has exactly $s - 1$ $U(1)$ factors, the number is

$$\frac{1}{m} \sum_{d|(n,m)} \sum_{j \geq 0} \phi(d) \binom{n/d + m/d - j - 1}{n/d - j} \binom{m/d}{j} \binom{jd}{s} (-1)^{j+s}.$$

It remains to be seen how this case of $(p, q) \neq 1$ would arise in the context of M-theory compactifications.

4. Counting vacua associated with symplectic groups

Here we derive the expressions analogous to those of Section 3, with unitary groups replaced by symplectic groups.

Every element in the symplectic group $Sp(n) = Sp(n, \mathbf{C}) \cap U(2n)$ is conjugate to an element in the maximal torus $T_{Sp(n)}$ given by

$$T_{Sp(n)} = \{(e^{i\theta_1}, \dots, e^{i\theta_n}, e^{-i\theta_1}, \dots, e^{i\theta_n})\}.$$

We need to count the number of inequivalent such elements x for which $x^m = 1$. Note that the first n diagonal entries determine the entire matrix. Also note that given a matrix in $T_{Sp(n)}$, replacing any θ_j by $2\pi - \theta_j$ results in an equivalent (i.e. conjugate) matrix. Therefore, we may restrict our attention to the first n entries, and to $\theta_j = \frac{2\pi j}{m}$, where $j = 0, 1, \dots, [\frac{m}{2}]$.

The arguments leading to Eq. (1) apply here with m replaced by $(\lfloor \frac{m}{2} \rfloor + 1)$, which is the number of possible entries on the diagonal, and with p replaced by n . We get

$$\binom{n + \lfloor \frac{m}{2} \rfloor}{n} \tag{6}$$

for the number of conjugacy classes of elements of order dividing m in $Sp(n)$.

In analogy with Eq. (3) we get

$$\binom{n-1}{s-1} \binom{\lfloor \frac{m}{2} \rfloor + 1}{s} \tag{7}$$

for the number of conjugacy classes of elements of order dividing m with s distinct conjugate pairs of eigenvalues, that is, s distinct θ_j in Eq. (4).

5. Counting vacua associated with orthogonal groups

In this section, we count the number of elements of order dividing q in all the orthogonal groups: $SO(2n)$, $SO(2n + 1)$, $O(2n)$ and $O(2n + 1)$. We discuss the odd and even values of q separately. The case of $SO(2n)$ corresponds to singularities of type D , and it counts semiclassical vacua on the moduli space of M-theory compactifications on singular G_2 spaces asymptotic to a cone over $(\mathbf{S}^3 \times \mathbf{S}^3)/\mathbf{D}_n \times \mathbf{Z}_q$.

5.1. Elements of odd order

Any matrix in $SO(2n + 1)$ is conjugate to an element of its maximal torus, given by

$$T_{SO(2n+1)} = \left\{ \text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_n), 1) \mid A(\theta) = \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix} \right\}. \tag{8}$$

Note that the matrix

$$\begin{pmatrix} B & & \\ & I_{2n-2} & \\ & & -1 \end{pmatrix},$$

where

$$B = \begin{pmatrix} 1 & \\ & -1 \end{pmatrix},$$

is an element of $SO(2n + 1)$ and conjugating by it takes θ_1 to $-\theta_1$ in $T_{SO(2n+1)}$. Similarly, replacing any θ_j by $-\theta_j$ in the expression for $T_{SO(2n+1)}$ leaves us in the same conjugacy class. Therefore, similar to the symplectic case, we may restrict our attention to $\theta_j = \frac{2\pi j}{q}$, $j = 0, 1, \dots, \lfloor \frac{q}{2} \rfloor$. As in Eq. (1), and now replacing p by n and q by $\frac{q+1}{2}$, we have

$$\binom{n + \frac{q+1}{2}}{n} \tag{9}$$

for the number of conjugacy classes of elements of order dividing q in $SO(2n + 1)$ for odd q . Physically, this represents the number of ways to break an $SO(2n + 1)$ gauge symmetry by a Wilson line of order q , where q is odd.

The maximal torus of $O(2n + 1)$ is different:

$$\begin{aligned}
 T_{O(2n+1)} &= \{T_1 = \text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_n), 1); \\
 &\quad T_2 = \text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_n), -1)\}.
 \end{aligned}
 \tag{10}$$

Since here q is odd, we cannot have -1 as an eigenvalue for any element of order q , so elements of T_2 are not relevant. Therefore, the counting remains the same as the $SO(2n + 1)$ case, and Eq. (9) holds.

Now consider $SO(2n)$. Here the maximal torus is

$$T_{SO(2n)} = \{\text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_n))\}.
 \tag{11}$$

It is no longer the case that replacing θ_i by $-\theta_i$ necessarily leaves us in the same conjugacy class because

$$\left(\begin{array}{c|c} B & 0 \\ \hline 0 & I_{2n-2} \end{array} \right) \notin SO(2n).$$

Instead, we must flip the signs of pairs of θ_i 's to stay in the same conjugacy class. To flip, say, θ_1 and θ_2 the conjugation would be via

$$\left(\begin{array}{cc|c} B & 0 & 0 \\ \hline 0 & B & 0 \\ \hline 0 & 0 & I_{2n-4} \end{array} \right) \in SO(2n),$$

so while $\text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_n))$ is conjugate to $\text{diag}(A(-\theta_1), A(\theta_2), \dots, A(\theta_n))$ in $O(2n)$, it is not so in $SO(2n)$ unless at least one of the θ_j is 0. This makes the counting considerably more complicated in $SO(2n)$ than in $O(2n)$. We start with the easier case, $O(2n)$.

In $O(2n)$, the maximal torus is

$$\begin{aligned}
 T_{O(2n)} &= \{T_1 = \text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_n)); \\
 &\quad T_2 = \text{diag}(A(\theta_1), A(\theta_2), \dots, A(\theta_{n-1}), B)\}.
 \end{aligned}
 \tag{12}$$

Since q is odd and the order of any element in T_2 is even, we can ignore T_2 for this case. Now, since

$$\left(\begin{array}{c|c} B & 0 \\ \hline 0 & I_{2n-2} \end{array} \right) \in O(2n),$$

flipping any single θ_j leaves us in the same conjugacy class, as was the case for $SO(2n + 1)$.

So we can restrict to $\theta_j = \frac{2\pi j}{q}$, $j = 0, 1, \dots, [\frac{q}{2}]$, giving

$$\binom{n + [\frac{q}{2}]}{n}
 \tag{13}$$

for the number of ways to break $O(2n)$ gauge symmetry by a Wilson line of order q , where q is odd.

In going from $O(2n)$ to $SO(2n)$, in some cases two elements that are in the same conjugacy class in $O(2n)$ may be in two distinct conjugacy classes in $SO(2n)$. These are the elements of T_1 in the maximal tori of $SO(2n)$ or $O(2n)$ for which $\theta_j \neq 0 \forall j$. The number of such elements x with $x^q = 1$ is

$$\binom{n + \frac{q+1}{2} - 1}{n}. \tag{14}$$

This formula is obtained by replacing $\frac{(q+1)}{2}$ by $\frac{(q+1)}{2} - 1$ in Eq. (9), as the number of allowed eigenvalues is one less (since zero is not allowed).

The number of elements in $O(2n)$ with $x^q = 1$ and at least one $\theta_i = 0$ is

$$\binom{n - 1 + \frac{q+1}{2}}{n - 1}. \tag{15}$$

This formula is derived by fixing $\theta_1 = 0$ and counting the number of elements in T_1 of order dividing q , allowing the $\theta_{j>1}$ to take on any of the $\frac{q+1}{2}$ possible values. It is equivalent to replacing n by $n - 1$ in Eq. (9).

To get the number of conjugacy classes in $SO(2n)$ of order $q = 2m + 1$, we multiply formula (14) by 2 and add formula (15) to get

$$2 \binom{n + \frac{q-1}{2}}{n} + \binom{n + \frac{q-1}{2}}{n - 1} = \binom{n + \frac{q+1}{2}}{n - 1} \frac{n + q - 1}{n}, \tag{16}$$

which physically is the number of ways to break $SO(2n)$ gauge symmetry by Wilson lines of odd order q . This case of $SO(2n)$ includes the important GUT group $SO(10)$, which is obtained when the G_2 manifold has a D_5 singularity, as constructed in [8]. Note that the formulas for $O(2n)$, $O(2n + 1)$, and $SO(2n + 1)$ are identical, but differ from the formula for $SO(2n)$.

Now let s be the number of distinct θ_i that appear in Eqs. (8), (10), (11), or (12).

In analogy with Eq. (3), we get

$$\binom{n - 1}{s - 1} \binom{\frac{q+1}{2} + 1}{s}$$

for the number of conjugacy classes of elements of order dividing q in $O(2n)$, $O(2n + 1)$, or $SO(2n + 1)$ with s distinct θ_i 's.

For $SO(2n)$, the counting is again more complicated. We count separately the conjugacy classes that have at least one $\theta_i = 0$, and those that do not. If the angle 0 does not appear, the number of elements of order dividing q with eigenvalue number s is

$$\binom{n - 1}{s - 1} \binom{[\frac{q}{2}]}{s} \tag{17}$$

and as before we will multiply this by 2. If the angle 0 does appear, we have $s - 1$ distinct angles left to be determined:

$$\binom{n - 1}{s - 1} \binom{[\frac{q}{2}]}{s - 1}.$$

So the total number of conjugacy classes of elements of order dividing q in $SO(2n)$ with s distinct θ_j is

$$\binom{n - 1}{s - 1} \left[2 \binom{\frac{q+1}{2}}{s} \binom{\frac{q+1}{2}}{s - 1} \right]. \tag{18}$$

As in the case of unitary groups, the number s here has physical significance as it is related to the number of $U(1)$ factors that appear in the remaining group H . Given the relation

$$U(n) = O(2n) \cap Sp_{2n} \mathbf{R},$$

one can rewrite an element in the even part of $T_{O(2n)}$ as $\text{diag}(e^{i\theta_1} I_{n_1}, \dots, e^{i\theta_s} I_{n_s}) \in U(n)$ where $\sum_{j=1}^s n_j = n$ and n_j is the number of times θ_j appears. Then the commutant of this element in $U(n)$ is

$$\prod_{j=1}^s U(n_j) = U(1)^s \times \prod_{j=1}^s SU(n_j),$$

so in $O(2n)$ the commutant of that element has at least s $U(1)$ factors.

5.2. Elements of even order

For $SO(2n + 1)$, all the arguments that applied for odd q apply for even q as well. For $O(2n + 1)$, since q is even, we do have to add the elements of type T_2 in the torus. But the counting is exactly the same as that in T_1 . So we have

$$\binom{n + \frac{q}{2}}{n} \tag{19}$$

for the number of conjugacy classes of elements of order dividing $q = 2m$ in $SO(2n + 1)$, and

$$2 \binom{n + \frac{q}{2}}{n} \tag{20}$$

for that number in $O(2n + 1)$.

Now we turn to $O(2n)$. Again, in addition to the counting in T_1 , we also have to count inside T_2 . For T_2 , note that we have $n - 1$, not n , 2×2 blocks of the form $A(\theta_i)$. We obtain

$$\binom{n + \frac{q}{2}}{n} + \binom{n + \frac{q}{2} - 1}{n - 1} \tag{21}$$

for the number of conjugacy classes of elements of order dividing $q = 2m$ in $O(2n)$.

For $SO(2n)$, the maximal torus consists only of elements of the form T_1 . However, flipping θ_j to $-\theta_j$ does not leave us in the same conjugacy class unless at least one θ_j is either 0 or π so that $A(\theta_j)$ commutes with B (note that in the previous subsection where q was odd, $\theta_j = \pi$ was not allowed). So now we need to count separately the elements in the torus that have no $\theta_j = 0, \pi$, multiply this number by 2, and add to that the number of elements that do have at least one $\theta_j = 0, \pi$. Our counting methods, together with some algebra of binomial coefficients, leads to

$$\binom{n + \frac{q}{2}}{n} + \binom{n + \frac{q}{2} - 2}{n} \tag{22}$$

We now consider the number of conjugacy classes of order $q = 2m$ with a fixed number s of distinct values of θ_i in the torus. We have

$$\binom{n - 1}{s - 1} \binom{\frac{q}{2} + 1}{s}$$

for $SO(2n + 1)$,

$$2 \binom{n - 1}{s - 1} \binom{\frac{q}{2} + 1}{s}$$

for $O(2n + 1)$,

$$\left[\binom{n-1}{s-1} + \binom{n-2}{s-1} \right] \binom{\frac{q}{2}+1}{s}$$

for $O(2n)$, and

$$\binom{n-1}{s-1} \left[\binom{\frac{q}{2}+1}{s} + \binom{\frac{q}{2}-1}{s} \right]$$

for $SO(2n)$.

6. On symmetry breaking patterns: Wilson vs. Higgs

Patterns of symmetry breaking by Wilson lines are generally considered to be the same as patterns of symmetry breaking by a related adjoint Higgs field. However, there is a subtle but significant difference which we point out here.

As explained in Section 2, when a gauge symmetry G is broken by a Wilson line U , the remaining group H is given by the centralizer of the Wilson line in the group,

$$H = C_G(U) = \{h \in G \mid hUh^{-1} = U\}.$$

On the other hand, in symmetry breaking by a Higgs field, the remaining group is the one generated by the commutant of the Higgs field in the Lie algebra,

$$H = \exp(\{X \in \mathfrak{g} \mid [\phi, X] = 0\}).$$

We now show that even with the simple identification $U = e^\phi$ between a Wilson line and a Higgs field, the symmetry breaking patterns are not the same. The difference is rooted in the fact that in general, conjugation in the Lie group is not in one-to-one correspondence with commutation in the Lie algebra. Specifically, let $X \in \mathfrak{g}$ and let $U_t = e^{t\phi}$, $h_t = e^{tX}$ form one-parameter subgroups of the Lie group. Then

$$h_t U_t h_t^{-1} = U_t \tag{23}$$

does not always imply

$$[\phi, X] = 0. \tag{24}$$

Rather, this is true only when t is small; when t is not small, (23) may be satisfied while (24) is not. We demonstrate this by a simple explicit example. Let $\phi = \text{diag}(\pi i, -\pi i) \in \mathfrak{su}(2)$. Then $U = e^\phi = -I$, which is in the center of the group $SU(2)$ so does not break it. But ϕ is not in the center of the Lie algebra $\mathfrak{su}(2)$; it commutes only with its diagonal elements. Hence, the symmetry breaking pattern arising from an adjoint Higgs field can be different from that arising from the corresponding Wilson line – at the group level, more symmetry may be preserved. Therefore, one should take extra care in applying the formulas obtained here for Wilson lines to symmetry breaking by Higgs fields.

This allows us to use Wilson lines to study certain GUT symmetry breaking patterns that are not allowed by Higgs fields and obtain the Standard Model group in new ways [42].
